

TRAVELING VOICES

TECHNICAL INFORMATION

Traveling voices is a sound installation that allows the visitors to explore the sound landscape of the city above the Malmö Citytunnel

The installation is made by two lines of wood/plexiglass where a set of **infra-red diodes** are placed. Over the lines a block shape is placed. This block contains a **Infra-red LED emitter** that will be aligned with the photodiodes when moving, allowing us to know the relative position of the block.

This diodes are connected to an **arduino board** that communicates with the computer running a piece of software written in openFrameworks.

The computer receives the current position of the block and plays the sounds of the city that are approximately above the tunnel in that relative position between the two extremes

The sound of each line is distributed to two speakers via a two-channel soundcard.

The kind of speakers and and the sound-card depend on the possibility of borrowing them from K3.
